

(a) The advantage holds at every chain length

(b) ...and widens as the chain lengthens

All three solvers reach the target $\approx 100\%$; the gap is entirely self-collision avoidance. $n = 1000-5000$ per cell (16 DOF re-run at the larger n ; rare events); bands are Wilson 95% intervals. Every ratio in (b) is significant at $p < 0.05$ (Fisher exact).
